How much context is enough?
Two cases of span-conditioned stem allomorphy

Jason Merchant
2014; to appear in *Linguistic Inquiry*

Abstract

Greek voice and aspect jointly condition verbal stem allomorphy, including suppletion. Negation and tense in English do likewise. These cases show that stem allomorphy cannot be restricted to cases where the conditioning element is structurally adjacent to the element that displays allomorphic variation. But neither is contextual allomorphy entirely free from locality constraints: allomorphy can be conditioned only by a *span*: a contiguous set of heads in an extended projection.¹

The conditions on allomorphic variation, including suppletion, play a central role in debates about the nature of the interaction between phonology and morphology and between theories that are localist versus those that are globalist. One of the central arguments for one version of a localist architecture comes from a putative generalization that selection of allomorphs is strictly local, a claim I will call the *Node Adjacency Hypothesis*: in particular, that the appearance of a particular outward-sensitive allomorph µ can be conditioned only by morphosyntactic features of an element that is linearly adjacent to µ. In this paper, I present two cases of outward-sensitive allomorph selection that require access to morphosyntactic

¹Thanks especially to Anastasia Giannakidou for extensive discussion of the Greek. I am particularly indebted to Karlos Arregi, Jonathan Bobaljik, Vera Gribanova, Greg Kobele, Jack Hoeksema, Andrew Nevins, and Peter Svenonius for valuable comments and suggestions. Thanks also to the reviewers for *Linguistic Inquiry*, whose comments and questions led to substantial improvements in argument and presentation.
features of nodes that are not adjacent to the allomorph, from Greek and from English, and show that an alternative generalization using the notion of spanning, the *Span Adjacency Hypothesis*, can capture these cases without permitting a range of unattested allomorphic variation.

1 Voice and aspect-triggered stem allomorphy in Greek

It is a commonplace assumption that viewpoint (or ‘grammatical’ or ‘outer’) aspect (such as imperfective, perfective, progressive, habitual) is encoded by a head that takes a verbal projection as its complement, with the goal of giving a compositional semantics to such aspects (see Giannakidou 2009 for one set of proposals for Greek and references):

1. \[ vP = \lambda e. P(e) \]
2. a. \[ \text{PERFECTIVE} = \lambda P_v t . \lambda i. \exists e_v[P(e) \& \tau(e) \subseteq i] \]
   b. \[ \text{IMPERFECTIVE} = \lambda P_v t . \lambda i. \exists e_v[P(e) \& Q_t(t \subseteq i)[t \subseteq \tau(e)]] , \]

where \( Q = \forall \) (for the progressive reading) or GEN (for the habitual)

Such a semantics is designed to work with a syntax such as the following:

\[ T = \lambda P_v t . \lambda i. \exists e_v[P(e) \& \tau(e) \subseteq i] \]

It is also well known that many languages mark such aspectual distinctions morphologically on the verb, through prefixes (as in Slavic) or suffixes (as in Romance, Greek, and Slavic), through a stem alternation, or through a combination of these. This latter pattern is found in Spanish, for example, where the verb

---

2This tree includes a standard ordering of the functional projections in the clause, including Tense > Aspect > Voice, from Rivero 1990, who is the first to my knowledge to have proposed a separate VoiceP, and a separation of Voice from v, following Collins 2005, Merchant 2013, Harley 2013, Alexiadou et al. In preparation, and many others.
querer ‘to want’ has quis- as its perfective stem, and quer- as the imperfective one; these stems combine with inflectional affixes that index person and number of the subject but also differ by tense, mood, and aspect (-e for 1s past indicative perfective, and -ía for 1s past indicative imperfective):

\[(4)\]
\[
a. \text{Yo quisé ir al circo.} \quad \text{I wanted.PERF.1s go.to.the circus ‘I wanted to go to the circus.’}
\]
\[
b. \text{Yo quería ir al circo.} \quad \text{I wanted.IMPERF.1s go.to.the circus}
\]
\[
\text{‘I {wanted/used to want} to go to the circus.’}
\]

Assuming a syntactic structure like the one in (3) above, accounting for the stem-selecting property of aspect is straightforward in a theory such as Distributed Morphology, as articulated for example in Embick 2010. In Spanish, either V-v-Voice forms a unit targeted by Vocabulary (or Lexical) Insertion (because these nodes are subject to the putative operation of Fusion, discussed below in section 2 and indicated here with subscripts), or Voice, because it lacks exponence in Spanish, has been ‘Pruned’ (using the operation defined in Embick 2010:59); accordingly, we simply posit the following context-sensitive allomorphs:

\[(5)\]
\[
a. \text{WANT}_{V+v(+\text{Voice})} \rightarrow \text{kis-} / \text{Asp[+Perf]}$
\]
\[
b. \text{WANT}_{V+v(+\text{Voice})} \rightarrow \text{ker-}
\]

This analysis, conditioning the allomorphy as it does by the features of the adjacent node, conforms to the constraints to this effect that have long been proposed in the literature—versions of this constraint are proposed in Siegel 1978, Allen 1978, Embick 2010, and Bobaljik 2012.\footnote{Bobaljik, for example, moots two versions of locality. The first, given in (6), bans allomorph selection in a head \(\alpha\) by a head \(\beta\) if \(\beta\) is separated from \(\alpha\) by the boundary of a maximal projection. The second version bans root allomorphy from being triggered by \(Y\) across \(X\) even when these heads form part of a single complex head, as in (7):}

\[\beta\]
Bobaljik 2012:13 suggests that the adjacency constraint holds only of root allomorphy, as here, not of affixal allomorphy, but in any case the Spanish examples satisfy the constraint.

Embick 2010 (see also Embick 2012 for application to Spanish agreement-triggered ablaut) presents a strong theory of contextual allomorphy based on how Vocabulary Insertion (VI) operates; he posits two conditions that will be of interest here. Condition A1 is essentially from Bobaljik 2000, and condition A2 makes use of Embick’s notion of concatenation, a term is used in other ways in the literature (being sometimes defined over nonterminal nodes as well; for this reason, I will refer exclusively to linear adjacency instead).5

5 The conditions in (8) and (9) are taken verbatim from Embick 2012, but the ideas are found in Embick 2010. For example, A1 is stated as follows in Embick 2010, p. 42: “Vocabulary insertion applies first to the most deeply embedded node in a structure and then targets outer nodes successively.” A2 is “a morpheme can show contextual allomorphy determined by another morpheme only when these two pieces are linearly adjacent to one another” (p. 15) (alternatively, “Contextual allomorphy is possible only with elements that are concatenated,” p. 16).

(8) (A1) Insertion proceeds from the inside-out.
(9) (A2) Contextual allomorphy requires concatenation (linear adjacency).

Embick 2012 illustrates the predictions of this theory schematically with reference to the following complex head:

(10) Complex head:
He writes (Embick 2012:26):

By (A1), VI occurs first at X, then at Y, then at Z. Thus, ... VI at Y could in principle see either phonological or morphosyntactic features of X but can look “outwards” only to morphosyntactic features of Z; and so on. In short, a node may show inward sensitivity to either morphosyntactic or phonological features, but it may show outward sensitivity only to morphosyntactic features ... by (A2) insertion at e.g. X could only be affected by √ROOT or Y. The reason for this is that only the Root and Y are concatenated with X.

Embick shows that is possible to analyze the well-known alternations involving diphthongization in certain Spanish stems (pens-, piens- vs. tens-, tens-) as a result of morphologically triggered but stress-conditioned phonological rules, and not as stem allomorphy at all (but see Bermúdez-Otero 2013 for a spirited rebuttal). Such an approach is unlikely to extend to the aspect-sensitive alternations (which are quite heterogeneous phonologically and lack any kind of phonological conditioning), but the analysis posited above does not seem to run afoul of the locality principles in any case, as the Aspect head is plausibly adjacent to the (complex) head which shows the allomorphy.

Such a simple analysis cannot, however, be extended to Greek. Although Greek verbs have differing stems that are sensitive to aspect, Greek also has a synthetic active/nonactive voice distinction with an overt exponent. The selection of the stem depends on the combination of voice and aspect, precisely the situation ruled out by Embick’s system.

The morphology of the modern Greek verb is well studied, and the verbal alternations are thoroughly identified in standard grammars, such as the compre-
hensive Holton et al. 1997 (see also Galani 2005 and Spyropoulos and Revithiadou 2009 for theoretical treatments and references). The verbs fall into three classes for the purposes of our discussion: suppletive stem verbs, regular verbs, and irregular (but nonsuppletive) verbs.

Greek has three transitive verbs that show aspect/voice-conditioned suppletion: _troo_ ‘eat’, _vlepo_ ‘see’, and _le(γ)_o ‘say’. These verbs, like irregular verbs, have three stems: for _troo_, for example, the stem _fa(γ)_- is the active perfective stem, _faγo_- is the nonactive perfective stem, and _tro(γ)_- is used otherwise, and is known as the imperfective stem.

(11) Greek suppletive stem verbs

<table>
<thead>
<tr>
<th>imperfective stem</th>
<th>active perfective stem</th>

</tr>
<tr>
<td>le(γ)-</td>
<td>p-</td>
<td>lex-0-/ipo-0-</td>
<td>‘say’</td>
</tr>
</tbody>
</table>

These stems combine with a regular set of endings to yield the full paradigm, here illustrated with _troo_:

(12) Greek suppletive stem verb _troo_ ‘I eat’

7The stem-final γ is dropped in certain combinations under conditions, at least partially register-based, that I will not investigate here; I also neglect to indicate regular allophonic variation in the realization of γ, which is palatalized before the front vowels. Here and throughout I also ignore variant endings and omit discussion of the distribution of the past active augment, the stressed initial é-, which occurs when the stem-endings has no antepenult to bear stress, but which has an irregular form in a few verbs conditioned by aspect which deserve an investigation of their own (óél-o ‘want’ imperf.past í-ðel-a, perf.past ðelis-a; ksér-o ‘know’ í-kser-a, í-kser-a; pín-o ‘drink’ é-pín-a, í-pí-a; vlép-o ‘see’ é-vlep-a, í-ð-a; lé-o ‘say’ é-leý-a, í-p-a; and cf. the vocalic augment verbs like éx-o ‘have’ í-x-a, í-x-a. See Spyropoulos and Revithiadou 2009 for a recent analysis of the augment in Distributed Morphology.
Lexical insertion rules sensitive to these features can be provided as follows, assuming that the Elsewhere principle will apply to prohibit (13c) from applying if either of (13a,b) can:

(13) a. $\sqrt{\text{EAT}} \rightarrow \text{fa(γ) / __ Voice[+Act] Asp[+Perf]}$
    b. $\sqrt{\text{EAT}} \rightarrow \text{faγo / __ Voice[−Act] Asp[+Perf]}$
    c. $\sqrt{\text{EAT}} \rightarrow \text{tro(γ)}$

Such context-sensitive rules clearly violate the locality conditions on contextual allomorphy as defined above: the environments for insertion make reference

---

8 Treating -su as a portmanteau is not crucial here. It is traditional to segment this as s-u, with -u being the 2nd singular nonactive imperative suffix and -s- the perfective morpheme; this segmentation may well be right, but given that -s- appears in this form where the perfective does not otherwise show -s- (though see below for verbs that do), the usual simple segmentation requires additional justification.
to an element that is not in the local—that is, immediately adjacent—context. It is impossible to correctly determine which stem should be used without access to the aspectual information given by the Aspect head, but this head is separated from the stem by the Voice head. This is not a problem in languages like Russian or Spanish, where the alternations are not sensitive to voice, only to aspect: the combined head V-v-Voice is adjacent to Asp in those languages (or Voice is ‘pruned’), and so lexical insertion rules can be made appropriately sensitive to the value of the feature on Aspect (see Gribanova To appear for one approach to Russian secondary imperfective aspect consistent with the Node Adjacency Hypothesis). But in Greek, the perfective nonactive morpheme -θ- is overt, and thus trying to write equivalent rules for Greek leads to (13), *quod non erat demonstrandum*.

The strength of this argument depends, of course, on the correctness of the morphological analysis given by the segmentations in (12). A different segmentation might be proposed that would vitiate the argument against the Node Adjacency Hypothesis: if it in fact were the case that -θ- were part of the stem (a complex stem perhaps the result of a further operation), then the selection of that complex stem could be conditioned on simple adjacency to the aspectual head. In fact, what I have given in (11) in the third column as the nonactive perfective stem + affix, Holton et al. 1997 give as a single combined stem: e.g., *faγοθ-, iđoθ-, lexθ-/ipoθ*. But conflating the stem with the affix like this obscures the perfectly regular nature of the affix. The only possible reason one might have for claiming it is part of the stem is that there is a small subset of verbs that lack -θ- in the nonactive, the athetic verbs, whose properties I discuss at greater length below. But such minority cases in no way obviate the fact that -θ- is otherwise a regular affix, any more than irregular past forms such as *sang* mean that -d is not the regular past tense affix in English. I therefore follow the vast majority of researchers in separating the -θ- from the stem.

The examples thus far are compatible with positing -θ- as a realization of the nonactive voice head Voice[-Act] under Asp[+Perf]. The latter head, when occurring with Voice[-Act] and Tense[Past], can then be analyzed, as Rivero 1990 does, as being realized in the nonactive by -ik-, leaving the past personal endings (-a, -es -e, -ame, -ate, -an) as the contextually determined realizations of T(Agr) (these endings are the elsewhere endings: they are blocked in the nonactive imperfective by a set of more specific endings, as we will see below). Consistent with such an approach are the entries in (15), operating on a complex head resulting from V-movement into T as in (14).

(14)  \( V(-v)\)-Voice-Aspect-Tense
The difficulty that this set of assumptions presents for Embick’s constraints can be seen by attempting to follow them to the letter to generate a particular form. Take for example a putative step-by-step derivation of the past nonactive perfective 1st singular form like faγo-θ-ik-a ‘I was eaten’ from (12) above. In (16), the output of successive-cyclic head movement from V to T yields an appropriate complex head with the requisite morphosyntactic feature bundles. By (8) (A1: ‘Insertion proceeds from the inside-out’), Vocabulary Insertion must start at √EAT, selecting from among the three stems tro(γ)-, fa(γ), faγo-. But choosing the correct stem—the nonactive perfective faγo—would require that we access the features of both Voice and Aspect, and thus contravenes (9) (A2: ‘Contextual allomorphy requires concatenation’).

c. Tns[Past]; φ[1s] → a Tns[Past]; φ[1p] → ame
d. Tns[Past]; φ[2s] → es Tns[Past]; φ[2p] → ate
e. Tns[Past]; φ[3s] → e Tns[Past]; φ[3p] → an

Perhaps the difficulty lies in assuming that Vocabulary Insertion accesses hierarchical representations like (16) at all. Another common assumption is that Vocabulary Insertion accesses a representation that has undergone Linearization (see Arregi and Nevins 2012 and Haugen and Siddiqi 2013a for detailed proposals). Linearization is the operation that maps the hierarchical geometry of an object like (16) to a simple ordered n-tuple of terminal nodes, as in (17). With such a representation, each of the contextually specified morphemes needed—faγo, θ, ik, a—can be inserted in satisfaction of their required environments and of A2. But it is unclear then what content A1 has: how is the notion of ‘inside out’, which
is defined on the geometry, to be reconstructed on an n-tuple? It cannot be: the hierarchical information is by design lost in Linearization.  

(17) a. $\sqrt{EAT} \to [\text{Voice}:-\text{Act}] \to [\text{Asp}:+\text{Perf}] \to [\text{T:Past};\phi:1s] \to (\text{Insert } f\text{a}yo-)$:

b. $f\text{ay}o \to [\text{Voice}:-\text{Act}] \to [\text{Asp}:+\text{Perf}] \to [\text{T:Past};\phi:1s] \to (\text{Insert } -\theta-) $

c. $f\text{ay}o-\theta \to [\text{Asp}:+\text{Perf}] \to [\text{T:Past};\phi:1s] \to (\text{Insert } -ik-)$:

d. $f\text{ay}o-\theta-ik \to [\text{T:Past};\phi:1s] \to (\text{Insert } -a) $(f\text{ay}o\theta_ik) $

e. $f\text{ay}o-\theta-ik-a$

One might try to rescue the Node Adjacency Hypothesis by making use of the fact that $-\theta-$ is adjacent to the stem and that this morpheme by itself only appears in perfective nonactives. One could update the insertion rule for roots as follows, replacing (13b) by the following:

(18) $\sqrt{EAT} \to f\text{ay}o / _-\theta$

But this would be in clear violation of Embick’s implementation of (A1), which bans outward-looking phonological sensitivity.

These cases of suppletion also put paid to any possibility of entertaining the idea that true suppletion is limited to functional elements or categories, and is not found with lexical categories. This idea is stated in Embick 2012:84, who writes, “Marantz ... [has] emphasized that in a theory with some late insertion, restricting suppletion to the functional vocabulary is an important desideratum.” (Compare also “Roots are not (by hypothesis) subject to Vocabulary Insertion” (Embick 2010:53) and “…it is not possible for Roots to show suppletion” (Embick and Halle 2005:6, emphasis in original.).) Embick goes on to discuss go/went and be, claiming that such cases are “light verbs” and as such “members of the functional vocabulary” (p. 84). But no independent reason for classifying these as $\nu$ and not as regular verbal roots is given, nor is any citation to any work that makes such an argument given. (One could cite here van Riemsdijk 2002, who however does not argue that all instances of go are ‘light’ in his sense.) It is furthermore extremely unlikely that a compound verb like undergo/underwent, which shows the same suppletion in English, could plausibly be classified as a ‘member of the

While Arregi and Nevins 2012 argue persuasively that there are vocabulary entries whose insertion contexts must be conditioned by linear adjacency of nodes, relaxing the Node Adjacency Hypothesis to be stated over such linearizations, not hierarchical structures, would still require access to the content of nonadjacent nodes.
functional vocabulary’.

See also Veselinova 2006, Corbett 2007, Siddiqi 2009, Bobaljik and Harley 2012, Haugen and Siddiqi 2013b, and Harley (To appear) for more discussion and numerous counterexamples.

The second set of verbs in Greek that are problematic for the Node Adjacency Hypothesis are the irregular ones. These verbs show stems that display a variety of irregularities, including apophony, augmentation, truncation, and combinations of these: Holton et al. list 132 such verbs from the first conjugation alone (pp. 169-175). Selected examples drawn from Holton et al.’s list include the following:

Interestingly, Greek lexical compounds formed from the suppletive verbs do not use the suppletive stems: antileγ- ‘argue against’ (nonpast active perfective antilek-s-), διαλεγ- ‘choose’ (diak-lek-s-), ek-leγ- ‘elect’ (ek-lek-s-), epi-leγ- ‘select, cull’ (epi-lek-s-), pro-leγ- ‘predict’ (prolek-s-); apo-vlep- ‘intend, aim’ (apo-vlep-s-), epi-vlep- ‘supervise’ (epi-vlep-s-), para-vlep- ‘(negligently) fail to see’ (para-vlep-s-), pro-vlep- ‘predict’ (provlep-s-), pro-vlep- ‘expect/hope for’ (pros-vlep-s-). Transparent compounds, however, do: para+le-o ‘exaggerate’ (para+p-); kata+trot(γ) ‘eat up’ (kata+fα(γ)-). It would be appealing to attribute these differences to different heights of attachment of the prefixes: low attachment of a prefix in a lexical compound blocks suppletion, while high attachment in transparent ones allows it.

10 Interestingly, Greek lexical compounds formed from the suppletive verbs do not use the suppletive stems: antileγ- ‘argue against’ (nonpast active perfective antilek-s-), διαλεγ- ‘choose’ (diak-lek-s-), ek-leγ- ‘elect’ (ek-lek-s-), epi-leγ- ‘select, cull’ (epi-lek-s-), pro-leγ- ‘predict’ (prolek-s-); apo-vlep- ‘intend, aim’ (apo-vlep-s-), epi-vlep- ‘supervise’ (epi-vlep-s-), para-vlep- ‘(negligently) fail to see’ (para-vlep-s-), pro-vlep- ‘predict’ (provlep-s-), pro-vlep- ‘expect/hope for’ (pros-vlep-s-). Transparent compounds, however, do: para+le-o ‘exaggerate’ (para+p-); kata+trot(γ) ‘eat up’ (kata+fα(γ)-). It would be appealing to attribute these differences to different heights of attachment of the prefixes: low attachment of a prefix in a lexical compound blocks suppletion, while high attachment in transparent ones allows it.

These verbs raise the same issue that the suppletive verbs did above: the form of the stem is determined by the aspect of the verb, but by hypothesis, this aspectual node is not adjacent to the stem in the nonactive. While in the active perfective and in the imperfective, one could claim that Voice was 'pruned,' making Aspect adjacent to the stem, such a move is not feasible in the nonactive perfective, given the overt exponent of Voice, -θ-.

One possibility that arises for analyzing these alternations that is not available for the suppletive cases would be to invoke morphophonological ‘readjustment rules.’ For example, Embick 2010:99f. posits a morphophonological readjustment rule to handle the unexpected appearance of the aorist morpheme -se- in place of -sa- in the classical Greek optative active 2sg, 3sg, and 3pl, which is triggered by a nonadjacent agreement affix. While it is obvious that there is no uniform mor-

---

11 As a result of a more general manner dissimilation rule, -θ- is realized as τ after a continuant, though in certain archaic forms, dissimilation does not occur.
phonological rule that would derive the alternations in (19), perhaps a slew of them could do the trick. But Embick fails to give any criterion for distinguishing between true allomorphy, analyzed with Vocabulary Insertion of competing morphemic exponents as in (13), and the effects of such putative ‘readjustment rules’. As Bobaljik 2012:140 refreshingly puts it, “In theory, there is a sharp division of labor between rules of exponence and readjustment rules... Of course, there is a difficult grey area for the analyst in establishing just where the boundary lies; alternations like many – mo-re could be treated formally as suppletion ... or as the output of a very powerful readjustment rule, rewriting the syllable rime.” (Bobaljik himself eschews readjustment rules entirely in his analyses of comparatives. See also Haugen and Siddiqi 2013a for a critical discussion of the explanatory power of readjustment rules, and compare the unmincing condemnation in Bermúdez-Otero 2013:83: “DM [Distributed Morphology] routinely ... resort[s] to devices, like the unconstrained use of readjustment rules, that blur the line between allomorphy and phonology, and destroy the empirical content of the theory.”) Without a criterion for deciding when a morphophonological readjustment rule is involved, and when simple allomorphy, the appeal to unspecified readjustment rules threatens to be no better than Justice Stewart’s famous criterion for recognizing pornography (‘I know it when I see it’) and becomes subject to Stainton’s (2006) criticism (of elliptical repair effects): it becomes a ‘get-out-of-counterexample-free card’.

We can thus conclude, with Joseph and Smirniotopoulos 1993 and Holton et al. 1997 that for these verbs at the least, three distinct stems must be posited. For the regular verbs, Holton et al. 1997 also claim that there are three stems involved, just as there are with the suppletive and irregular verbs. They list (pp. 156-158) twenty-two different patterns for the three stems for regular 1st conjugation verbs, and an additional seven for 2nd conjugation verbs, for a total of twenty-nine classes; these are given in (20), with the 1st conjugation verbs listed in rows 1-22, and the 2nd conjugation verbs in rows 23-29. With the exception of classes 14-19, the active perfective stem ends in the familiar -s, inherited from the ancient Greek sigmatic aorist, which I will follow Ralli (Ralli 1998, 2003, 2005; cf. Philippaki-Warburton 1973) and many others (and as is also traditional, and as

---

12 Note that I am not making the stronger claim that readjustment rules do not exist at all: as a reviewer points out, they may provide one insightful way to model analogical change that a total assimilation of irregular stems to suppletion may not (depending on how we wish to model analogy, of course). The important point for present purposes is simply that in terms of the theory presented in Embick 2010, potential appeal to readjustment rules makes the strong locality claims embodied in the Node Adjacency Hypothesis unfalsifiable.
Holton et al. themselves do on p. 18) in analyzing as a separate morpheme (the realization of Asp[+Perf] in the context of Voice[+Act]).

</table>
While ten of these classes also seem to require the positing of three stems (classes 1, 3, 8, 10, 13, 17, 22, 24, 25, 29), another eighteen need only two stems (since the alternations $p\sim f$ and $k\sim x$ are regular), or even one (class 15).

For a regular two stem verb, then, such as $\text{dénō}$ ‘I tie’, there is an imperfective stem ($\text{dēn}$-) and a perfective one ($\text{đe}$-). The full paradigm is given in (21).

</table>

We can then posit a lexical entry for -$s$- as the realization of Aspect[+Perf] in regular verbs in the active voice, as in (22):

(22) Asp[+Perf] → $s$ / Voice[+Act]

\(^{13}\)Such stems are also used in the formation of other forms, including the gerund $\text{đēn-ondas}$, the active perfect participle $\text{đē-s-i}$, the nonactive perfect participle $\text{đe-0-i}$, the resultative participle $\text{đe-ménos}$, the result nominal $\text{đē-simo}$, and the present participle, which does not exist for this verb, but would be formed from the imperfective stem by adding the endings -$on$, -ousa, -on.

\(^{14}\)Active perfective -$s$- could be argued to appear also after some irregular stems as well: $\text{apelavn}$-, $\text{apila-s}$-, $\text{apela}$- ‘deport’; $\text{đin}$-, $\text{đo-s}$-, $\text{đo}$- ‘give’; $\text{priz}$-, $\text{prik-s}$-, $\text{pris-t}$- ‘swell’; $\text{soz}$-, $\text{so-s}$-, $\text{so}$- ‘save’; $\text{đet}$-, $\text{đe-s}$-, $\text{te}$- ‘place’ (this last could be classified as a two-stem verb if Grassman’s law is assumed to be operative in the synchronic grammar).
On the model of the lexical entries in (13), we have the following:

(23) a. √TIE \rightarrow \delta e / __ Voice Asp[+Perf]  
b. √TIE \rightarrow \delta en

If the conditioning environment in (23a) is correct\(^{15}\), then these forms also show that the Node Adjacency Hypothesis cannot be maintained: we have a V stem alternation that is conditioned in part by the morphosyntactic features of Aspect, separated from V-v by Voice.\(^{16}\)

But this structure is isomorphic to the Spanish examples given above in (5): if ‘pruning’ is allowed, then we can prune the Voice node (or feature bundle), and the result reduces to the analysis of the Spanish.

Notice that even Pruning does not help in the case of the perfective nonactive form ðe-θ-o. On the analysis mooted, this form would have the following structure:

Since the crucial node that conditions the alternation is the Aspect node, it cannot be pruned before it conditions the insertion of the perfective stem ðe-. The fact that it itself has a null exponent, making it eligible for Pruning, is entirely irrelevant to the computation: it must be present in order to condition the selection of the stem, and it is separated from that stem by the overt exponent of Voice, -θ-. This is precisely the configuration we saw above with respect to the verbs in (19) that posed a problem for the Node Adjacency Hypothesis. Thus even the

\(^{15}\)An even simpler statement, as pointed out by a reviewer, would be √TIE \rightarrow \delta e / __ \{s, θ\}. But such a statement violates (8), which prohibits outward sensitivity to phonological features. Note that one could not replace s, θ in this statement by their morphosyntactic feature bundle equivalents (V oice[−Act], Asp[+Perf]), since it is only -θ- that conditions ðe-, not V oice[−Act] per se, which is also present in the imperfective nonactive.

\(^{16}\)One could try to propose that aspect in fact is closer to the stem than voice, as Hamp 1961 and Warburton 1970 do, but this would have several problems: first, it would be incompatible with standard compositional semantic analyses; second, it would seem to conflate viewpoint aspect with lexical aspect; third, it would not ameliorate the difficulty for Embick’s proposals—all it would do is reverse the two heads that are jointly needed to condition the alternations.
While pairs like (24) and (25) might suggest that Greek Voice and Aspect nodes are in fact the same node in some way (given standard reasoning from their complementary distribution), and that collapsing the two nodes would provide a way to save the Node Adjacency Hypothesis (assuming counterfactually that we could ignore the implications for the compositional semantics that provide some of the best reasons for positing the articulated syntactic structure to begin with), there are reasons to be doubtful such a solution is feasible. Recall that there are forms in which both the Voice node and the Aspect node have overt exponents: the nonactive perfective pasts in -θ-ik- illustrated in (17) above, for example, in which -θ- is the usual Voice[−Act] and -ik- realizes Aspect[+Perf]. It is worth noting that both elements occur independently. We have already seen forms in which -θ- occurs without -ik-; there are also verbs in which -ik- occurs without -θ-, the so-called athetic verbs:

These verbs take the expected perfective affix -ik- and the regular past endings, yielding for example the following forms for kέο ‘I burn’:

(27) Greek athetic verb kέο ‘I burn’

17There is also a regular passive perfective stem klef-t-, but it has the nontransparent meaning ‘elope’. This is an interesting reversal of the often noted pattern of an irregular form maintaining or acquiring a narrower or unpredictable semantics, while the regular form is compositional: e.g., brothers vs. brethren; older vs. elder; worked vs. wrought, etc.
For these stems, we could propose a null version of -θ- and introduce a dia-
critic on the stem that conditions it, as Embick 2010 does for distinguishing those
French prepositions that show portmanteau forms with the definite article (à+le
> au, de+le > du). As Svenonius 2012 points out, however, the relevant rules are
extremely powerful, and as such bear a severe burden of proof over alternatives
that might exist.

18 Most verbs that have a 2sg nonactive perfective imperative in fact form this imperative using the active
perfective stem, e.g. váf-su ‘paint yourself’ (not *vaf-su), vrék-su ‘wet yourself’ (not *
vra-x-su), although the 2pl nonactive perfective imperative uses the nonactive stem as expected
(e.g., váf-t-íte ‘paint yourselves’, vra-x-t-íte ‘wet yourselves’). This -su appears even with verbs
that do not take -s- in the past perfective, such as apomákrín-su ‘remove yourself’ (cf. apomákrín-
a [active.perfective.past.1sg]; apomakrino is a one-stem verb). This fascinating peculiarity and
its implications for locality of stem selection, overwriting, etc., deserve a fuller investigation: it
appears that a node as far away as Mood is affecting stem selection.
Similarly for the active perfective verb forms that lack \(-s\): recall that most of the irregular verbs, as well as the regular classes 14-19 and the suppletive verbs, do not co-occur with the morpheme \(-s\). On a traditional analysis, these verbs must be distinguished with a diacritic that blocks the insertion of \(-s\), or else we posit a null variant of Asp[+Perf] for them.

Rivero 1990 gives a syntactic decompositional account of these alternations, with an independent one-to-one mapping of morpheme to syntactic head (see also Tsimpli 2006, Kallulli 2007, Alexiadou et al. In preparation), but Joseph and Smirniotopoulos 1993 (see also Ralli 1998) argue that such an approach fails to account for the complex interaction between aspect, tense, voice, and the stem we have just observed, in particular the many patterns of allomorphy. They suggest instead that each verb realizes a unordered set of feature values, without a one-to-one mapping of syntactic or morphological nodes to morphemes.

But Embick and others are right in the suggestion that we do not want or expect a theory in which ‘anything goes’, as an unfettered morphological realizational theory of multiple exponence could allow (but see Stump 2001 for an inferential realizational theory and how constraints on such could be stated). Detailed examination of allomorphic patterns has shown that there are locality constraints on allomorphy. One such is identified in Bobaljik’s (2012) magisterial investigation of the allomorphy possibilities found in comparatives and superlatives: only a contiguous string of adjacent heads can be targeted for Vocabulary Insertion, and hence for allomorphy, including especially suppletion.

Bobaljik’s analysis provides the first explanation for the fact that while there are regular morphological comparatives and superlatives (tall, taller, tallest; stem pattern: A A A), suppletive ones (bad, worse, worst; pattern: A B B), including suppletion in all three forms (Latin bonus, melior, optimus; pattern: A B C), there are no attested forms that follow the pattern *A B A (e.g., good, better, goodest) or *A A B (e.g., good, gooder, best). This follows if the superlative is built on the comparative: [[[Adj] CMPR] SUP], and only an adjacent span can be subject to suppletion.

But as Svenonius 2012 is right to insist upon, contiguity is still a relatively weak notion, potentially allowing all sorts of interactions that appear not to be attested.¹⁹ He follows and expands on a hypothesis articulated in Williams 2003, such potential but unattested interactions might include a wide variety of actual contingencies, such as the form of an adjective being determined by an adjacent complementizer it selects (e.g., a hypothetical pair like *Abby is angry₁ but Abby is angry₂ that it’s raining where angry₁ and angry₂ would be allomorphs) or a complementizer having a particular form depending on whether the adjacent determiner of the subject of its clause is definite or indefinite (e.g., that₁ the man left

¹⁹
Abels and Muriungi 2008 (where the relevant notion is labeled a ‘stretch’) and Taraldsen 2010 (who gives further references for precursors to the idea, going back to McCawley 1968), that locality for purposes of lexical insertion is not defined by intervening heads per se or only by phase or phrasal boundaries but by spans. A span is a set of syntactic categories in an extended projection, and Svenonius states the spanning hypothesis as in (29).

(28) Let $T$ be an ordered n-tuple of terminal nodes < $t_1,\ldots,t_n$ > such that for all $t \in T$, $t = t_1$ or $t$ is an element of the extended projection\(^{20}\) of $t_1$.
   a. For all $k = 1\ldots n, t_k$ is a span. (Every node is a trivial span.)
   b. For any $n > 0$, if $t_k$ is a span, then < $t_k,\ldots,t_{k+n}$ > is a span.

(29) **Spanning Insertion Hypothesis**: A span and only a span can be targeted for Vocabulary Insertion.

For example, consider the heads in the extended projection of V in Greek: V v Voice Asp T (setting aside Mood and Neg (or Σ), which are only analytic and occur above T in Greek). Each of these, by (28a), is a span (a trivial, one-membered one). By (28b), the following are the nontrivial spans:

(30) Spans in the verbal extended projection in Greek:
   <V, v> <v, Voice> <Voice, Asp> <Asp, T>
   <V, v, Voice> <v, Voice, Asp> <Voice, Asp, T>
   <V, v, Voice, Asp> <v, Voice, Asp, T>
   <V, v, Voice, Asp, T>

Not every possible n-tuple formed from the set of heads in the extended projection of V is a span; for example, none of the following are spans: <V, T>, <V, v, Asp>, <Voice, T>, <V, Asp>, <Asp, Voice> (see Svenonius 2012 for discussion of general constraints on lexicalizations).

Svenonius puts the Spanning Insertion Hypothesis as follows:

\(^{20}\)See Grimshaw 2005 for details: an extended projection consists of a totally ordered set of projections, each of whose heads selects one of the other projections, except for the lexical head, and up to and including a determined highest projection. Familiar examples are PP, DP, NumP, and NP in the nominal domain and TP, AspP, VoiceP, vP, VP for the verbal domain. Abels and Muriungi 2008:719 are agnostic on whether spans should be any set of selecting heads, or only those within a single extended projection: “We suggest that a morpheme can realize a stretch of functional heads; by a stretch we mean one or more heads that select each other’s maximal projections.”
“[M]orphological exponents are always associated with spans, trivial or nontrivial ... A single morphological exponent (morpheme, for short) cannot spell out two heads (cannot “span” two heads) unless those heads are in a complement relation with each other. Thus, a single morpheme cannot spell out a head in an extended projection together with all or part of a specifier, nor can a single morpheme spell out a head in an extended projection together with all or part of an adjunct.” (Svenonius 2012:3)

One intuition behind spans is similar to the one behind Relativized Minimal-ity (Rizzi 1990): one effect of the theory is that an allomorph can be triggered by a distant head only if the allomorphy affects all intervening heads as well.21 But while spans mimic in some ways possible paths of head movement, they do not require head movement, so the overt position of the verb in the extended projection is not relevant to the morphological spell-out that targets the span it is in: head movement may feed Vocabulary Insertion, but it need not. In Greek, where Roussou and Tsimpli 2006 and Alexiadou and Anagnostopoulou 1998 among many others (including Rivero 1990) have argued that verbs move up to T, the resulting complex head is the input to Lexical Match (L-Match), indicated with wavy lines, and Vocabulary Insertion:

21This effect can be achieved using the idea in Kobele 2012 for handling suppletion and morphological spell-out as well; in his proposal, contiguity of structure mirrors order of application of derivational operations, leading to similar predictions about constraints on allomorphy. Similarly, a strict version of categorial grammar applied to morphology, such as that in Hoeksema 1985, might make similar predictions.
(31)  *faɣo-θ-ik-a* ‘I was eaten’

Note that the use of spans as insertion criteria does not alleviate the difficulty for the Node Adjacency Hypothesis: the Vocabulary Item *faɣo-* in (31) is the non-active perfective stem, and its appearance must be conditioned by the Voice[−Act] and Aspect[+Perf] node in combination.

Eschewing null nodes and pruning, spanning allows us to posit structures like the following for the active perfective nonpast, where *ðe-* could be posited to lexicalize the span V-v-Voice[+Act]:

(32)  *ðe-s-o* ‘I (will) tie’
While this representation does away with the positing of a null realization for Voice[+Act], it does so at the expense of the simple two-stem solution for such verbs, since we would then also need to posit a separate vocabulary entry (also known as a vocabulary item) δe- that would realize only √TIE+v, in order to allow for its appearance in the nonactive perfective past: δé-θ-ik-α. Since my goal here is not to present a theory of vocabulary entry insertion, but rather to illuminate the constraints on the conditioning environments of such insertions, I will not attempt to adjudicate between the two possibilities that arise: either we posit (as before) a null affix to realize Voice[+Act] (yielding the familiar δe-∅-s-o, as above) or we posit that -s- itself realizes a span of Voice[+Act]-Asp[+Perf], as in (33). Either option is compatible with my contention that the Greek facts show that the Node Adjacency Hypothesis is inadequate.

(33) δé-s-o ‘I (will) tie’

The athetic stems in (26) above might be better candidates for a representation along the lines of (32):
The result in these cases thus is something close to that mooted for Spanish in (5) above, either by Fusion (see the next section for discussion) or ‘Pruning’ of nodes that have no phonological material associated with them (devices the spanning analysis is designed to eschew). Recall that the crucial case from regular, two-stem verbs like δένω ‘I tie’ came from nonactive perfective nonpast forms such as δέ-θ-ό, which has the following structure:

(35)  δέ-θ-ό ‘I (will) be tied’
Note that one could assume, as mooted above for -s- in (33), that -θ- here lexicalizes the span Voice[−Act]-Asp[+Perf], but doing so would run afoul of the same consideration that led us away from thinking δe- could ever lexicalize Voice: we would have to posit two vocabulary entries with θ as their phonology: one for Voice[−Act]-Asp[+Perf] here, and one for simple Voice[−Act] when followed by the past perfective -ik- as in δé-θ-ik-a.

The Spanning Insertion Hypothesis allows us also to account for the portmanteau inflectional morphemes used in Greek. While the Tense/Agreement portmanteau morphemes may seem to be too mundane to be commented on (they exist of course also in English, French, Spanish, German, and many other languages), one particular set demonstrates clearly the advantages of the theory. The nonactive imperfective endings come in two varieties: one set, in (36a), are those used in the nonpast (‘I am being eaten’, etc.), and the other, in (36b), are used in the past (‘I was being eaten’, etc.):

(36) Greek nonactive imperfective verbal desinences

<table>
<thead>

</tbody>
</table>

As Joseph and Smirniotopoulos 1993 point out, these endings are maximal portmanteaux: they are specific to the imperfective, and indicate voice, tense, and the features of the subject. They lexicalize the span Voice-Asp-T(Agr); these nodes taken together, crucially, do not form a constituent:
(37)  *troy-ómun* ‘I was being eaten’

Such examples are also important in showing that the spanning theory of lexical insertion is not just another way of coding insertion at non-terminal nodes, as in Neeleman and Szendrői 2007, Caha 2009, Radkevich 2010, and Haugen and Siddiqi 2013a. In such theories, which also have as one of their goals the elimination of operations such as fusion and the positing of null morphemes, lexical insertion can target a non-terminal node if and only if the morpheme corresponds to all and only the features dominated by that node. In cases where the span includes the lowest node in a complex head (as in (31) and (34)), the empirical coverage will be the same as in spanning. But when the lowest node is not included, the difference in applicability of the two theories becomes apparent: spanning can target a sequence of nodes as in (37), but there is no non-terminal node that would qualify for insertion. This is because the highest node (dominating Tense) also dominates the root, but the root is not part of the portmanteau (though see Radkevich 2010 and Haugen and Siddiqi 2013a for attempts to address this point as well): the nodes spanned here do not form a constituent.

We can thus revisit the assessment of Joseph and Smirmiotopoulos 1993: “such an approach ... is nothing more than a morphological solution masquerading as a syntactic one; in particular ... what guarantees that the order of morphemes as they are realized is the same as their order of ... addition?” (pp. 393f.). The answer to such criticisms is that constraints on syntactic verb movement or, as here, on spans, are exactly what guarantees morpheme order and, crucially, the kinds of portmanteauism that can be found. Accounts like the one given in Joseph
and Smirniotopoulos 1993 (see also Embick 2012 for further examples of such approaches), on which “individual stems are available to be ‘invoked’ by inflectional rules that refer to an unordered set of particular morphosyntactic features” (p. 396), is exactly the kind of unconstrained account that authors from Embick and Bobaljik to Arregi, Nevins, and Svenonius are at pains to point out the shortcomings of. It is, ultimately, an empirical question what morphosyntactic categories and feature sets a given language makes use of, and what kinds of morphological realization these will have in the language, including allomorphic variation. What an analysis using an ‘unordered set of ... morphosyntactic features’ cannot do is rule out any possible combination resulting in multiple exponence. For \( n \) binary-valued features, we would potentially expect \( 2^n \) possible portmanteau morphemes, with any features that are not expressed in a nonmaximal portmanteau being expressed with potentially regular exponents. Constraints such as contiguity, or, as here, spanning, cannot be stated (or rather, they can be stated only as ad hoc feature cooccurrence restrictions: nothing about the geometry or structure of the features need inform such restrictions). At present, it does not seem that the considerable power of such a theory is warranted by the data.

But while important, whether or not spanning is the best way to capture the distribution of portmanteau morphemes or to regulate lexical insertion is not directly germane to the primary question addressed in this paper. The present focus is on the conditions on allomorph selection, not on the mechanisms of allomorph insertion themselves: the Spanning Insertion Hypothesis is a hypothesis about which nodes can be targeted for lexical insertion or be realized by a single morpheme. But whether or not the Spanning Insertion Hypothesis in (29) is correct, it does not bear on the the Node adequacy of the Node Adjacency Hypothesis, which is a hypothesis about which nodes may condition an allomorph. In other words, we need a constraint to replace the failed Node Adjacency Hypothesis: the notion of spanning gives us the requisite theoretical tool to state a more accurate, empirically adequate hypothesis:

\[ \text{(38) Span Adjacency Hypothesis:} \]

Allomorphy is conditioned only by an adjacent span.

This hypothesis permits nonadjacent heads and their features to participate in the conditioning of an allomorph, but requires that such nonadjacent heads (or their features) form a span with heads (or their features), up to and including the head that is adjacent to the conditioned form.\(^{22}\) This lets in a restricted amount

\(^{22}\)See Bobaljik 2012:223 fn. 10 for a discussion of the Icelandic strong verbs which suggest an “adjacency-by-transitivity effect” similar to the one seen here in Greek.
of nonadjacency, and meets the desideratum of not letting just any kind of non-
adjacent head condition allomorphy. Allomorphy is indeed conditioned locally,
but not, as the Node Adjacency Hypothesis had it, only by the features of adja-
cent nodes, but rather by those in adjacent spans, whether or not those spans are
themselves lexicalized by vocabulary entries.

It may be helpful to visualize the competing hypotheses schematically. Con-
sider a complex head or a span consisting of nodes \( N_1 \ N_2 \ N_3 \ N_4 \). The Spanning
Insertion Hypothesis claims that the possible targets for lexical insertion are all
and only the ten groups given in (39a); no other possible combinations (e.g., \( N_1 \ N_3 \), etc.) are licit targets for insertion.

(39) In a span \( N_1 \ N_2 \ N_3 \ N_4 \), the following are the only possible targets for
lexical insertion:
1. \( N_1 \)
2. \( N_2 \)
3. \( N_3 \)
4. \( N_4 \)
5. \( N_1 \ N_2 \)
6. \( N_2 \ N_3 \)
7. \( N_3 \ N_4 \)
8. \( N_1 \ N_2 \ N_3 \)
9. \( N_2 \ N_3 \ N_4 \)
10. \( N_1 \ N_2 \ N_3 \ N_4 \)

The Node Adjacency Hypothesis (without pruning) predicts that only adja-
cent nodes can condition insertion. For example, if \( N_1 \) and \( N_2 \) were to be jointly
realized by a morpheme, only \( N_3 \), but not \( N_4 \), could influence the form of that
morpheme. The Span Adjacency Hypothesis, on the other hand, would allow \( N_3 \)
and \( N_4 \) to jointly condition the form realizing \( N_1 \) and \( N_2 \); it would also allow just
\( N_3 \) to play such a role; it would ban \( N_4 \) from conditioning the form of \( N_1 + N_2 \) if
the features of \( N_3 \) were not involved.\(^{23}\) Schematically, where \( \mu \) realizes \( N_1 \) and
\( N_2 \), we have the following:

(40) Possible conditioning environments for \( \mu \) under the ...

\(^{23}\)Including this constraint is important: without it, the Span Adjacency Hypothesis could be
easily vacuously satisfied by the inclusion of multiple intervening nodes that play no role at all in
conditioning the allomorphy. The constraint must be that no otiose nodes are included: that every
node in the conditioning span is required, and that no conditioning environment could be stated
that included less information.
The Span Adjacency Hypothesis is thus compatible with the vocabulary insertion rules in (13) above, repeated here, which posit three stems:

\[(41)\]

- \(\sqrt{\text{EAT}} \rightarrow \text{fa}(\gamma) / \_\_ \text{Voice}[+\text{Act}] \text{Asp}[+\text{Perf}]\)
- \(\sqrt{\text{EAT}} \rightarrow \text{fay}o / \_\_ \text{Voice}[-\text{Act}] \text{Asp}[+\text{Perf}]\)
- \(\sqrt{\text{EAT}} \rightarrow \text{tro}(\gamma)\)

The conditioning environments in (41a,b) consist of the span Voice-Aspect. Recall that at the point at which the rules in (41) apply, the nodes Voice and Aspect have not yet undergone lexical insertion. There are no morphemes in those nodes, only morphosyntactic feature bundles. It is the values of these features that jointly condition the stem allomorphy, not particular morphemes that may or may not realize Voice and Aspect. The conditioning span need not be the same as a span that is targeted for lexical insertion. Indeed, in this case, we can see clearly that the two are separate: Voice and Aspect are not jointly targeted for lexical insertion in the form \(\text{fay}o-\theta-\text{ik}-a\), whose structure is given above in (31).

2 Affixal negation and tense in English

The conclusion that nonlocally triggered stem allomorphy exists can also be reached by examination of the affixal negation (see Zwicky and Pullum 1983) of English, -n’t.

This can be seen for example in the forms don’t [dɒnt] and won’t [wɒnt], which appear in place of the expected *[dunt] (< do /dju/ + n’t /nt/) and *[wIln’t] (< will /wIl/ + n’t /nt/).24

But the most spectacular stem allomorphy triggered by negation comes in the behavior of negation with be. Many dialects of English have positive and negative variants of be (Bresnan et al. 2007). This is well known for the present tense, where suppletive ain(’t) [en(t)] is the uniform negative form of am, is, are, has,

\[24\] Also the irregular forms can’t [kænt], shan’t [ʃænt], and mustn’t [mʌstn’t], as Zwicky and Pullum 1983 point out.
have (e.g., I ain’t happy; they ain’t had breakfast yet), and in certain dialects, also of did (e.g., I ain’t know that). The pattern is laid out in the following:

(42) English dialectal positive and negative present tense forms of be, have

<table>
<thead>
<tr>
<th></th>
<th>positive</th>
<th>negative</th>
</tr>
</thead>
<tbody>
<tr>
<td>am</td>
<td>ain’t</td>
<td>ain’t</td>
</tr>
<tr>
<td>are</td>
<td>ain’t</td>
<td>ain’t</td>
</tr>
<tr>
<td>is</td>
<td>ain’t</td>
<td>ain’t</td>
</tr>
<tr>
<td>have</td>
<td>ain’t</td>
<td>ain’t</td>
</tr>
<tr>
<td>has</td>
<td>ain’t</td>
<td>ain’t</td>
</tr>
</tbody>
</table>

There are also varieties that show this pattern in the past tense. These varieties, such as that illustrated here in (43)\(^{25}\), show two forms of the past tense of be, depending on whether affixal negation is present or not\(^{26}\):

(43) a. I/you/he/she/it/we/y’all/they [waz] angry about it.
    b. I/you/he/she/it/we/y’all/they [wədn] angry about it.

This is similar to the pattern found in parts of the British Isles (Nevins and Parrott 2010) and in Southeastern coastal American English from Maryland and Virginia to North Carolina (Wolfram 2004a:292). Trudgill 2004:145 gives the following paradigm for the dialect of East Anglia:\(^{27}\)

(44) East Anglia positive/negative be

<table>
<thead>
<tr>
<th></th>
<th>singular</th>
<th>plural</th>
</tr>
</thead>
<tbody>
<tr>
<td>positive</td>
<td></td>
<td></td>
</tr>
<tr>
<td>I wus</td>
<td>we wus</td>
<td></td>
</tr>
<tr>
<td>you wus</td>
<td>you wus</td>
<td></td>
</tr>
<tr>
<td>he/she/it wus</td>
<td>they wus</td>
<td></td>
</tr>
<tr>
<td>negative</td>
<td></td>
<td></td>
</tr>
<tr>
<td>I weren’t</td>
<td>we weren’t</td>
<td></td>
</tr>
<tr>
<td>you weren’t</td>
<td>you weren’t</td>
<td></td>
</tr>
<tr>
<td>he/she/it weren’t</td>
<td>they weren’t</td>
<td></td>
</tr>
</tbody>
</table>

---

\(^{25}\)I do not know what the geographic or social distribution of these forms are, but I have heard them from speakers in rural and urban areas of the American Midwest and parts of the mid-Atlantic, at least.

\(^{26}\)The negative past is sometimes written ‘wont’, as in Wolfram 2004b:332 “The generalized past tense variant wont for wasn’t and weren’t in I wont there yesterday, found in some Southern vernacular varieties, is not typical of urban AAVE.”

\(^{27}\)Trudgill reports that the pronunciations of the ‘plural’ past in East Anglia can vary among /wɜːnt/, /wʌnt/, /wɔːnt/, and /wont/. 

30
The main difference between the variety represented in (43) and those of East Anglia and elsewhere is that the latter show a leveling that can be modeled with Impoverishment (to the singular in the positive past, and to the plural in the negative past, and including more complex patterns), as proposed by Nevins and Parrott 2010. But while (43) shows a similar leveling in the positive past, the negative form is not obviously related to any plural form.28

One common syntactic analysis compatible with selection facts and the possibility of these forms undergoing Subject-Auxiliary Inversion is to assume that the v/V complex raises through Neg to T, yielding the following structure:

(45)

```
TP
   /\    /
  T   NegP
    /\    /
   Neg  v
      /\    /
     v   T
        /\    /
       v   Tns:Past
          /\   /
         v   v
            /\   /
           √BE
```

The nodes in the complex head T in (45) can then be spelled out using lexical insertion rules that are sensitive to the presence of Neg (or, equivalently, the value of the Neg feature on a polarity head such as Σ):

(46)  a. √BE → wuz / __ v+T:Past  
      b. √BE → wudn / __ v+Neg+T:Past

---

28 One could suppose [w2dn] to be the result of a morphophonological rule of manner assimilation from a hypothetical /waz+n/ > [wadn]; such a rule would have to be morphophonologically restricted to occurring in this combination (and in the forms [sidn] (‘isn’t’), [s2dn] (‘doesn’t’)), as the otherwise similar ‘dozen’ /dzn/ surfaces as [d2zn], not as *[d2dn]. This would make the assimilation applying with negative affixation a derived environment effect. While I know of no particular evidence that favors or disfavors this route, it is clear that no such alternative analysis is possible for the suppletive ain’t.

31
Such rules, however, violate locality as posited above. One analytical option to avoid this conclusion is to use Fusion, an operation designed to map $n$ nodes hosting $n$ feature bundles onto a single node, as in (47).

(47) Fusion:

\[
\begin{array}{c}
\text{Neg} \\
\text{V} \quad \text{Neg} \\
\sqrt{\text{BE}} \quad [\text{Tns:Past}] \\
\end{array}
\xrightarrow{\text{Fusion}}
\begin{array}{c}
\text{T} \\
\text{Neg} \\
\sqrt{\text{BE}} \\
[\text{Neg:+}] \\
\end{array}
\]

This option is proposed in Chung 2007 to handle a similar phenomenon in Korean (see also Nevins and Parrott 2010 for application to English): in Korean, the verbs al- ‘to know’ and ess- ‘to be’, have suppletive negative stems, molu- and eps-, respectively, and do not occur with the usual preverbal short-form negator an(i)-. He proposes (p. 134) the Fusion of Neg and the V node to precede Vocabulary Insertion:

(48) Neg \[ +\text{neg} \] V \[ +\text{neg}, \text{EXIST} \] \xrightarrow{\text{Fusion}} Neg \[ +\text{neg} \] V \[ +\text{neg}, \text{EXIST} \] \xrightarrow{\text{Vocabulary Insertion}} Neg \[ +\text{neg}, \text{EXIST} \] /eps/

(49) \[ +\text{neg}, \text{EXIST} \] \xrightarrow{} /eps/

29Another possibility, which I will set aside here, would be to claim that /n/ is the Neg, which triggers manner of articulation assimilation on the final /z/, yielding /d/, as in the previous footnote. Such an approach would not extend to the weren’t replacement varieties, nor, assuming that T c-command Neg, would it ameliorate the locality problem of interest here.

30Turkish shows this pattern for the existential predicate var ‘there is’, with suppletive negative yok ‘there is not’ (cf. regular affixal negation -mA-), as in the following:

(i) a. Ev-de karpuz var-di.
   \textit{house-in watermelon exist-PAST}
   ‘There was watermelon in the house.’

b. Ev-de karpuz yok-tu.
   \textit{house-in watermelon not.exist-PAST}
   ‘There was no watermelon in the house.’
Chung argues that such an account better captures the scopal facts of negation (since semantically the negation can take wide scope, like clausal negation, over other elements; cf. German *kein*, Dutch *geen*), and similar facts can be adduced for the properties of the negative past copula in English. As Nevins and Parrott 2010, Radkevich 2010, and Haugen and Siddiqi 2013a point out, however, Fusion accounts require a conspiracy amounting to look-ahead: the syntactic operation of Fusion must apply in the syntactic derivation just in case there is a vocabulary entry that can realize those features in the morphology (that is, in order to block the otherwise regular expression of the nodes).

A second kind of analysis current in the literature proposed to handle such cases (as well as portmanteauisms) takes insertion of lexical material to be able to target non-terminal nodes (Neeleman and Szendrői 2007, Caha 2009, Siddiqi 2009, Radkevich 2010). These analyses do away with Fusion and do not suffer from look-ahead concerns. But as Haugen and Siddiqi 2013a discuss, insertion at non-terminal nodes leads to what they call the ‘containment’ problem: since a single vocabulary entry overwrites the node whose features it matches, including phrasal projections, the theory predicts that whenever this must occur, the root should allow for no internal arguments, a prediction that is clearly false, both for simple affixation (*solve-d the problem*, *proud-er of her analysis*), irregular stem changes (*understood the problem*), and suppletion (*underwent an operation*, *better at tennis*). (A reviewer notes correctly that this problem only arises on versions of nonterminal insertion theories that allow insertion at phrasal nodes; if the nonterminals are restricted to possibly complex heads, the ‘containment’ problem does not arise.) A second problem for these analyses is that they provide no way to handle portmanteau morphemes that do not include the root (such as the Greek past nonactive imperfective endings above), a phenomenon that spanning, as we have seen, can easily accommodate. (See Radkevich 2010 and Haugen and Siddiqi 2013a for modifications to non-terminal insertion theories that attempt to address these issues, however.)

Spanning, on the other hand, can give the following analysis:
The facts from English affixal negation, therefore, implicate a more expansive notion of locality than mere adjacency, a conclusion that is in line with a number of recent works (Svenonius 2013, Bermúdez-Otero 2013, Haugen and Siddiqi 2013a) that reach similar conclusions on quite different grounds.31

3 Conclusion

Non-locally conditioned stem allomorphy exists. But it only occurs conditioned by a span (a continuous sequence of heads in a single extended projection) and then only if the features of all the terminal nodes between the stem and the furthest terminal that conditions the allomorphy are implicated. The strong Node

---

31Jack Hoeksema points out to me that the distribution of the Dutch stem augment -er- with the stem kind ‘child’ in plurals may constitute another case of an allomorph being triggered by a nonadjacent morpheme. Although -er in modern Dutch has spread beyond its historical origin as a plural marker (being found in e.g., kind-er-lijk ‘child-like’, kind-er-actig ‘childish’, kind-er-kleding ‘children’s clothing’), with the noun kind itself, it occurs only in plurals. In particular, it does not occur before the diminutive suffix -tje unless that suffix itself is following by the plural morpheme:

(i) a. kind

\[\text{child} \rightarrow \text{child-er-PL ‘children’}\]

b. kind-je

\[\text{child-DIM ‘little child’} \rightarrow \text{child-er-DIM-PL ‘little children’}\]

Crucially, the singular form *kind-er-tje is rejected by many speakers (some appear to accept it; the argument against the Node Adjacency Hypothesis can only be made on the basis of those speakers who lack the form).
Adjacency Hypothesis is false, though the somewhat weaker Span Adjacency Hypothesis is compatible with the facts reviewed here.
